## Table of Contents

1. Synthetic Details.
2. The Phase Transformation of $\mathbf{1}$ to $\mathbf{2}$.
3. Single Crystal X-Ray diffraction data of $\mathbf{1 - 7}$ at 100(2)K.
4. Single Crystal X-Ray diffraction data of $\mathbf{1 - 7}$ at 296(2)K.
5. Bond lengths, angles and non-covalent interaction distances from 1-7.
6. Figures of 1-7.
7. Electrostatic potential of the $4-\mathrm{PPH}$ and $4,4^{\prime}-\mathrm{BipyH} / \mathrm{H}_{2}$ cations.
8. Experimental UV-Vis and luminescence spectra 1 - 7.
9. Low Temperature and calculated UV-Vis spectra of $\mathbf{3}$ and other related information.
10. Calculated Raman and IR spectra.
11. Experimental Raman and IR Spectroscopy.
12. Thermal ellipsoidal representations of $\mathbf{1 - 7}$.
13. References.

## 1. Synthetic Details:

## A Typical Synthetic Procedure for 1-7:

Uranyl nitrate hexahydrate (UNH $-0.100 \mathrm{~g}, 0.249 \mathrm{mmol}$ ) was dissolved in 5 mL of acetone and stirred in the presence of potassium thiocyanate ( $\mathrm{KSCN}-0.137 \mathrm{~g}, 1.49 \mathrm{mmol}$ ) for roughly 12 hours. A white crystalline solid $\left(\mathrm{KNO}_{3}\right)$ precipitated from the bright yellow solution and was discarded. The solution was heated and stirred until most of the solvent had evaporated and an orange or yellow solid remained. The solid was dissolved in DI $\mathrm{H}_{2} \mathrm{O}$ and stirred until a clear yellow solution persisted. Three molar equivalents of the appropriate pyridine were added to the solution. The solution was stirred, gently heated and acidified with 3 M HCl . Once the organic was completely dissolved, the solution was cooled, covered with perforated parafilm and left to evaporate under ambient conditions.

## Notes on the Synthesis of $\mathbf{1}$ and 3:

Compounds 1, $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, and 3, $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$, can be prepared directly and isolated as pure phases, yet $\mathbf{1}$ (post synthesis) is prone to dehydration and subsequently rearranges to form $\mathbf{3}$. The differences in the synthetic parameters that promote the formation of $\mathbf{1} \mathrm{vs} . \mathbf{3}$ are subtle and often overlap. The optimal conditions for promoting single crystal growth of $\mathbf{1}$ and $\mathbf{3}$ are provided in Table S1. Fluctuations in laboratory temperature due to seasonal changes seem to influence product formation, yet a quantitative correlation between temperature and product distribution could not be established.

Table S1. Optimal synthetic parameters for the formation of $\mathbf{1}$ and $\mathbf{2}$.

|  | $\mathbf{1 .}\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ | 2. $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$ |
| :--- | :--- | :--- |

| $\mathrm{H}_{2} \mathrm{O}$ | $7-8 \mathrm{~mL}$ | 10 mL |
| $\mathrm{pH}^{*}$ | $0.65-1.20$ | $1.20-1.40$ |

* Adjusted with 3M HCl.

Notes on the Synthesis of 3-7:

The initial pH and concentration of $\left[\mathrm{SCN}^{-}\right]$influences the relative product distribution of 3-7. The synthetic parameters provided in Tables S2 and S3 should be interpreted as guidelines to increase the likelihood of forming each phase 3-7. Preparing pure phases is difficult and co-crystallization is the norm. The low solubility of $4,4^{\prime}$-dipyridyl necessitates the ligand to water ratio be scaled accordingly. Note the role of temperature was not investigated in the synthesis of 3-7.

Table S2. Optimal synthetic parameters for the preparation of 3-5.

|  | $\begin{gathered} \text { 3: } \\ \left(\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{~N}_{2}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \end{gathered}$ | $\begin{gathered} 4: \\ \left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{1.5}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot 2 \\ \mathrm{H}_{2} \mathrm{O} \end{gathered}$ | $\begin{gathered} \hline 5: \\ \left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{2}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{4.75} \mathrm{Cl}_{0.25}\right] \\ \cdot \mathrm{SCN} \end{gathered}$ |

*Adjusted with 3M HCl

Notes specific to the synthesis of 3: $\left(\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{~N}_{2}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$

Compound $\mathbf{3}$ is the most frequently observed phase as it forms over a wide pH range: $0.8-3.5$. Syntheses of $\mathbf{3}$ performed between the pH range of $1.50-3.50$ results in maximum yields whereas the pH range of $3.0-3.5$ will typically produce a pure phase. All syntheses performed at or below pH 3.0 generally lead to co-crystallization of $\mathbf{3}$ with $\mathbf{4}$. Lower pH values $<1.3 \mathrm{and} /$ or allowing the mother liquor to approach or reach dryness typically leads to a mixture of 3-5 and 7 as determined by optical inspection and manual separation of the crystalline phases followed by PXRD.

Notes specific to the synthesis of 4 : $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{1.5}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$

Compound $\mathbf{4}$ is the second most frequently observed species and has a maximum yield over the pH range of 1.3 - 1.5. The crystallization of 4 typically occurs over the course of several weeks, yet prior to complete evaporation of the mother liquor. At or near dryness of the reaction media, compounds 5-7 co-crystalize with 4 and their respective product distributions appear to be influenced by the initial reaction pH and concentrations of: $\left[\mathrm{Cl}^{-}\right],\left[\mathrm{NCS}^{-}\right]$and $\left[\mathrm{UO}_{2}{ }^{2+}\right]$. Note this observation is only semiquantitative at best and based upon optical inspection of the post synthetic product distributions.

Notes specific to the synthesis of 5, $\left(C_{10} H_{10} N_{2}\right)_{2}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{4.75} \mathrm{Cl}_{0.25}\right] \cdot \mathrm{SCN}$, and 6, $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{2}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot \mathrm{NO}_{3}$

Compounds 5 and 6 were never synthesized as pure phases and formed only as part of cocrystallizations. The incorporation of one anion $\left(\mathrm{NO}_{3}^{-}\right.$vs. $\left.\mathrm{NCS}^{-}\right)$into the structures of $\mathbf{5}$ and $\mathbf{6}$ are seemingly influenced by the initial $\left[\mathrm{SCN}^{-}\right]$concentration. A six-fold excess of potassium thiocyanate (compared to UNH) favors the formation 5, whereas a twelve-fold excess favors the production of $\mathbf{6}$.

These phases tend to form as the mother liquor approaches dryness and after the formation of $\mathbf{3}$ and/or 4. We can thus speculate appreciable competition for ligand coordination to the remaining $\left[\mathrm{UO}_{2}{ }^{2+}\right]$ in solution exists as a function of depletion in the initial $\left[\mathrm{SCN}^{-}\right]$and an enrichment in $\left[\mathrm{Cl}^{-}\right]$concentration. This may explain the partial substitution of an isothiocyanate for that of a chloro ligand in $\mathbf{5}$, whereas no
substitution is observed when higher initial $\left[\mathrm{SCN}^{-}\right]$concentrations are utilized in $\mathbf{6}$. The incomplete precipitation of nitrate during synthesis is likely responsible for the incorporation of the $\mathrm{NO}_{3}{ }^{-}$anions in $\mathbf{6}$.

Table S3. Optimal synthetic parameters for the preparation of 6-7.

|  | $\mathbf{6 :}$ | $\mathbf{7 :}$ |
| :---: | :---: | :---: |
|  | $\left(\mathbf{C}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{9}} \mathbf{N}_{2}\right)_{3}\left[\mathbf{U O}_{2}(\mathbf{N C S})_{\mathbf{5}}\right] \cdot \mathbf{N O}_{3}$ | $\left(\mathbf{C}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{1 0}} \mathbf{N}_{\mathbf{2}}\right)_{\mathbf{2}}\left[\mathbf{\mathbf { U O } _ { \mathbf { 2 } } ( \mathbf { N C S } ) _ { 4 } \mathbf { C l } ] \cdot \mathbf { C l } \cdot \mathbf { 2 H } _ { \mathbf { 2 } } \mathbf { O }}\right.$ |
| UNH | 0.249 mmol | 0.249 mmol |
| KSCN | 2.51 mmol | $0.996-1.49 \mathrm{mmol}$ |
| $4,4^{\prime}-\mathrm{BIPY}$ | 0.747 mmol | 0.747 mmol |
| $\mathrm{H}_{2} \mathrm{O}$ | $8-10 \mathrm{~mL}$ | $8-10 \mathrm{~mL}$ |
| $\mathrm{pH}^{*}$ | $0.75-1.50$ | $0.50-1.25$ |

*Adjusted with 3M HCl
Notes specific to the synthesis of $7,\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{2}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{4} \mathrm{Cl} \cdot \mathrm{Cl} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right.$
Compound 7 typically co-crystallizes with $\mathbf{4}$, with the latter forming first. The depletion of [ $\mathrm{SCN}^{-}$] in the reaction media, due to the formation of 4 , combined with the already lower initial concentration of $\left[\mathrm{SCN}^{-}\right]$used (compared to $\mathbf{5}$ and $\mathbf{6}$ - Tables $\mathbf{S 2}$ and $\mathbf{S 3}$ ) likely contributes to the substitution of a chloro ligand in place of an isothiocyanate in the structure of 7. The lower initial pH value (compared to $\mathbf{5}$ and $\mathbf{6}$ ) likely provided a $\left[\mathrm{Cl}^{-}\right]$high enough to lead to the incorporation of a chloride anion and chloro ligand in 7.

## 2. The Phase Transformation of 1 to 2

Crystals or powder samples of compound 1, $\left(\mathrm{C}_{11} \mathrm{H}_{10} \mathrm{~N}_{3}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, are unstable outside of the mother liquor and are susceptible to dehydration and subsequent rearrangement to yield compound 2. The transformation of $\mathbf{1} \boldsymbol{\rightarrow} \mathbf{2}$ was monitored and studied via optical microscopy, powder and single crystal X-ray diffraction, the findings of each are described below. We note that large single
crystals of $\mathbf{2}$ can be prepared directly and are stable outside of their mother liquor as no phase transitions or degradation have been observed.

## Monitoring the phase transformation: Optical Microscopy and PXRD

Compound $\mathbf{1}$ is bright orange in color whereas compound $\mathbf{2}$ is bright yellow, these two phases can therefore be easily distinguished visually (Photo S1). A batch of orange crystals (of $\mathbf{1}$ ) was prepared and a portion of which was removed from the mother liquor and placed on a glass microscope slide and monitored via 10x optical microscopy. The crystals changed from bright orange to opaque and yellow (Photo S2). The opaque yellow crystals were analyzed via PXRD and determined to be purely composed of compound 2 .

Photo S1. The crystals of $\mathbf{1}$ (left) are orange whereas those of $\mathbf{2}$ (right) are yellow.

Photo S2. Left: Several orange crystals of 1 are in transition to yield 2, which is opaque and yellow. Right: An expanded view of a single crystal of $\mathbf{1}$ that is mid-transition to 2.

## Monitoring the phase transformation: Single Crystal and Powder X-ray Diffraction

An orange single crystal of $\mathbf{1}$ was isolated from the mother liquor and reflection data were collected to unit cell parameters determine: $\mathrm{a}=9.5941(8) \AA, \mathrm{b}=14.336(1) \AA, \mathrm{c}=16.243(1) \AA, \alpha=$ $94.758(1)^{\circ}, \beta=101.843(1)^{\circ}, \gamma=97.901(1)^{\circ}$. This crystal was then lightly crushed onto the center of a PXRD sample holder and allowed to sit in air for several minutes. After which, PXRD diffraction data were collected and the peak positions and intensities corresponded with that of compound 2 (Figure S1). PXRD analysis was performed as several attempts to first capture this transition on a single crystal were unsuccessful. The stress of the dehydration and subsequent rearrangement resulted in a polycrystalline sample. The loss in crystallinity is however, not instantaneous and as such, we captured the structure of 1M. The structure of $\mathbf{1 M},\left(\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$, is an intermediate between $\mathbf{1}$ and $\mathbf{2}$ and contains structural sentiments of both 1 and 2 (Figure S2).

Figure S1. The observed powder X-ray diffraction pattern of a crushed single crystal of $\mathbf{1}$ post transformation with the calculated pattern of $\mathbf{2}$ overlaid in blue.

## The data collection of 1 M .

A large crystal $(500 \mu \mathrm{~m})$ of $\mathbf{1}$ was cooled to 285 K under a $\mathrm{N}_{2}$ gas stream while reflection data were collected. The unit cell parameters of the crystal were determined in 10 minute intervals until the cell parameters no longer corresponded to $\mathbf{1}$. The crystal was immediately cooled to $100(2) \mathrm{K}$ and a full data set was collected, details are provided in Table S4. The stress caused by this transformation resulted in a gradual loss in crystallinity and as such, the final refinement contained several issues: most notably, regions of residual electron density, large $\mathrm{ADP} \min / \mathrm{max}$ rations and a failure of the refinement to converge. We are however, confident in the structural determination as the R values $\left(\mathrm{R}_{1} 12.75 \% \mathrm{wR}_{2}\right.$. 25.13\%) suggest a structurally correct model. Several of the 4-phenylpyridinium cations and isothiocyanate ligands in $\mathbf{2}$ were positionally disordered and required the use of PART instructions and individual atoms (e.g. C, N and S) required ISOR restraints. The U-N bond distances on U2 were restrained at $2.43 \AA \AA$ (DFIX) and refined using a free variable.

## Compound 1M: $\left(\mathrm{C}_{\mathbf{1 0}} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{5}\right]$

The $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ tectons form two distinct pairs, the first of which is formed by way of $\mathrm{S} \cdots \mathrm{S}$ interactions and are akin to those pairs observed in $\mathbf{1}$ whereas the second are formed via $\mathrm{S} \cdots \mathrm{O}$ interactions (Figure S3 and Table S5). The $\mathrm{S} \cdots \mathrm{O}$ interactions are much longer than the sum of the van der Waal radii
for S and O (at $120 \% \mathrm{vdW}$ ), yet are of note as these interactions are prominent in $\mathbf{2}$ and are therefore being observed prior to their formation (Figure S2). These two distinct types of $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ tecton pairs alternate and are linked to one another via $S \cdots S$ interactions, giving rise to chains that arrange parallel to one another and ultimately form an anionic layers in the (0-11) plane. The 4-PPH cations form columns via offset $\pi$-interactions, yet are disjointed as several of the cations are regularly displaced or contorted out-of-plane, disrupting the cationic stacking motif observed in 1 (Figure S4). The 4-PPH cations form several $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds to the uranyl tectons, relevant interaction distances and angles of which are provided in Table S5.

Table S4. Selected crystallographic parameters of 1M.

| Compound | 1M |

## 3. Single Crystal X-Ray diffraction data of 1 - 7 at $\mathbf{1 0 0 ( 2 ) K . ~}$

Single crystals of 1-7 were mounted on MicroMounts (Mitegen) and reflection data were collected using $0.5^{\circ} \omega$ scans at $100(2) \mathrm{K}$ on a Bruker SMART diffractometer equipped with an APEX II CCD detector with a Mo $K \alpha$ source (Table 1, of the main manuscript). The APEX II software suite ${ }^{1}$ was used to integrate the data and apply an absorption correction (SADABS). ${ }^{2}$ The structures were solved using direct methods via SHELXS ${ }^{3}$ and refined using SHELXL- $15^{4}$ within the WINGX software suite. ${ }^{5}$

Publication materials were prepared using EnCifer ${ }^{6}$ whereas figures of the title compounds were made using CrystalMaker v9.1.4. ${ }^{7}$

All of the non-hydrogen atoms in 1-7 were located using difference Fourier maps and refined anisotropically. The hydrogen atoms located on the carbon atoms of the pyridinium cations were placed in idealized positions and allowed to ride on their parent atoms. The hydrogen atoms associated with the nitrogen atom on each pyridinium cation 1 - $\mathbf{7}$ were located in difference Fourier maps, modeled, restrained (DFIX) and refined isotropically. The hydrogen atoms associated with the water molecules in $\mathbf{1}$ were located in the difference Fourier maps and modeled using DIFX (0.84 and 0.01) and DANG (1.32 and 0.04) restraints. There are two unique water molecules (Ow1 and Ow2) in 4, one of which (Ow1) was disordered over two positions and required the use of a PART command. The hydrogen atoms associated with both parts (Owla and Owlb) could not be located in the difference Fourier maps and were not modeled. The hydrogen atoms associated with Ow2 were located in the difference Fourier map and modeled using DFIX ( 0.84 and 0.01 ) and DANG (1.32 and 0.04 ) restraints.

An equatorial ligand site in 5 is partially occupied by an isothiocyanate (75\%) and chloro (25\%) ligand and required the use of a PART instruction. The resulting U-N (2.34(1) $\AA$ - Avg. of other U-N distances $2.433 \AA$ ) and U-Cl (2.980(9) $\AA$ ) bond lengths are shorter and longer, respectively, than expected, yet were not deemed egregious and were therefore not distance restrained.

The crystal used in the data collection of 7 was twinned and treated using Cell_Now. ${ }^{8}$ Two nonmerohedral twin domains ( $\sim 90: 10$ ) were found and are related by a $179.8^{\circ}$ rotation about [100]. The reflection data were integrated using SAINT $^{9}$ and an absorption correction was applied using TWINABS. ${ }^{10}$ Compound 7 contains two crystallographically unique solvent water molecules (Ow1 and Ow2) and although the hydrogen atoms associated with them were located in the difference Fourier maps, only those belonging to Ow1 could be modeled and required DIFX ( 0.84 and 0.01 ) and DANG (1.32 and $0.04)$ restraints.

## 4. Single Crystal X-Ray diffraction data of 1 - 7RT at 296(2)K.

Single crystals of $\mathbf{1 - 7}$ were mounted on MicroMounts (Mitegen) and reflection data were collected using $0.5^{\circ} \omega$ scans at $296(2) \mathrm{K}$ (note 1 was collected at $285(2) \mathrm{K}$ ) on a Bruker SMART diffractometer equipped with an APEX II CCD detector with a Mo K $\alpha$ source (Table S6). The APEX II software suite ${ }^{1}$ was used to integrate the data and apply an absorption correction (SADABS). ${ }^{2}$ The structures were solved using direct methods via SHELXS ${ }^{3}$ and refined using SHELXL- $15^{4}$ within the WINGX software suite. ${ }^{5}$ Publication materials were prepared using EnCifer ${ }^{6}$ whereas figures of the title compounds were made using CrystalMaker v9.1.4. ${ }^{7}$

All of the non-hydrogen atoms in 1RT - 7RT were located using difference Fourier maps and refined anisotropically. The hydrogen atoms located on the carbon and nitrogen atoms of the pyridinium cations were placed in idealized positions and allowed to ride on their parent atoms.

The hydrogen atoms associated with the three unique water molecules in 1RT were able to be located in the difference Fourier maps, yet were unable to be modeled and refined. There are two unique water molecules (Ow1 and Ow2) in 4RT, one of which (Ow1) was disordered over two positions and required the use of a PART command. The hydrogen atoms associated with both parts (Ow1a and Owlb) could not be located in the difference Fourier maps and were not modeled. The hydrogen atoms associated with Ow2 were located in the difference Fourier map and modeled using DFIX (0.84 and 0.01) and DANG (1.32 and 0.04) restraints. The hydrogen atoms associated with the water molecule (Ow1) in 7RT were modeled, yet required the use of DIFX ( 0.84 and 0.01 ) and DANG ( 1.32 and 0.04 ) restraints.

Crystals of 1RT are prone to phase transformation (i.e. dehydration followed by a structural rearrangement to yield 2RT) and as such, the highest temperature a full X-ray diffraction experiment could be conducted was $285(2) \mathrm{K}$; the crystal of 1RT ultimately underwent a phase transformation during the end of the data collection.

An S atom (S1) in 2RT was positionally disordered and required the use of a PART instruction. An equatorial ligand site in 5RT is partially occupied by an isothiocyanate (75\%) and chloro (25\%)
ligand and required the use of a PART instruction. The resulting U-N (2.34(1) $\AA$ - Avg. of other U-N distances $2.433 \AA$ ) and $\mathrm{U}-\mathrm{Cl}(2.980(9) \AA)$ bond lengths are shorter and longer, respectively, than expected yet were not deemed egregious and were not distance restrained.

The crystal used in the data collection of 7RT was twinned and treated using Cell_Now. ${ }^{8}$ Two non-merohedral twin domains ( $\sim 90: 10$ ) were found and are related by a $179.8^{\circ}$ rotation about [100]. The reflection data were integrated using $\operatorname{SAINT}^{9}$ and an absorption correction was applied using TWINABS. ${ }^{10}$ Compound 7RT contains two crystallographically unique solvent water molecules (Ow1 and Ow2) and although the hydrogen atoms associated with them were located in the difference Fourier maps, only those belonging to Ow1 could be modeled and required DIFX ( 0.84 and 0.01 ) and DANG (1.32 and 0.04 ) restraints.

Table S6. Selected crystallographic data pertaining to the 296K data collections of 1-7.

Cg refers to the center of gravity of an aromatic ring.
$\mathrm{Cg} 1\left(\mathrm{~N}_{6}\right.$ and $\left.\mathrm{C}_{6}-\mathrm{C}_{10}\right) . \mathrm{Cg} 2\left(\mathrm{C}_{11}-\mathrm{C}_{16}\right) . \mathrm{Cg} 3\left(\mathrm{~N}_{7}\right.$ and $\left.\mathrm{C}_{17}-\mathrm{C}_{21}\right) . \mathrm{Cg} 4\left(\mathrm{C}_{22}-\mathrm{C}_{27}\right) . \mathrm{Cg} 5\left(\mathrm{~N}_{8}\right.$ and $\left.\mathrm{C}_{28}-\mathrm{C}_{32}\right) . \mathrm{Cg} 6\left(\mathrm{C}_{33}-\mathrm{C}_{38}\right)$.
$\mathrm{Cg} \perp$ - The perpendicular displacement between two ring centroids measured from Cg 1 to the plane parallel with the second ring centroid.

Beta - The ring normal and the vector between the ring centroids.

Table S10. Selected offset $\pi$-interaction lengths and angles in 3.

| Interaction | Distance (£) | Perpendicular <br> Displacement | Distance (£) | Angle Beta <br> $\left({ }^{\circ}\right)$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Cg}_{1} \cdots \mathrm{Cg}_{1}$, | $3.8079(13)$ | $\mathrm{Cg}_{1} \cdots \mathrm{Cg}_{1} \perp \perp$ | $3.8056(9)$ | 1.6 |  |

## 6. Figures of compounds 3 - 7

Figure S5. Alternating layers of $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ and 4,4'-BipyH tectons in $\mathbf{3}$ occupy the (100) plane.

Figure S6. The $4,4^{\prime}$-BipyH cations in $\mathbf{3}$ form chains via $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds. The chains run parallel and are linked to one another by offset $\pi$-interactions.

The hydrogen bonding network of $4,\left(C_{10} H_{10} N_{2}\right)_{1.5}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right] 2 \mathrm{H}_{2} \mathrm{O}$ :
$\mathrm{A}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ anion is linked to a $4,4^{-}-\mathrm{BipyH}_{2}$ cation via a non-coordinated (lattice) water molecule (Ow2) that forms two bridging $\mathrm{O}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Figure $\mathbf{S} 7$ and Table S8). The $4,4{ }^{\prime}-\mathrm{BipyH}_{2}$ cation in turn forms a second $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond to a second water (Ow1) molecule that also forms a second $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond with its symmetry equivalent, $\mathrm{Ow}_{1}$ '. The symmetry equivalent ( $\mathrm{Ow} 1^{\prime}$ ) in turn forms a $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond to a second $4,4^{\prime}-\mathrm{BipyH}_{2}$ cation that is then bridged by way of another water molecule ( $\mathrm{Ow} 2^{\prime}$ ) to a $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ anion of an adjacent chain.

Figure S7. A complex hydrogen bonding network links the $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ tectons of neighboring 'double-wide' chains together. The remaining $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ tectons that comprise the chains have been omitted to highlight the hydrogen bonding network.

Figure S8. Top: Non-coordinated SCN anions in 5 accept both $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds from the doubly protonated $4,4-\mathrm{BipyH}_{2}$ cations to form sheets in the (100) plane. Bottom: The $4,4^{\prime}$ ' $\mathrm{BipyH}_{2}$ cations in $\mathbf{6}$ form $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds with the nitrate anions to form sheets in (100).

Figure S9. The 4,4 - BipyH $_{2}$ cations in 6 form $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds with the nitrate anions and $\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]^{3-}$ tectons.

Figure S10. The global structure of 7 (top) with views of the $S \cdots S$ interactions (bottom left) and hydrogen bonding interactions (bottom right) that give rise to the anionic and cation sheet motifs.

## 7. Electrostatic Potential of the $4-\mathrm{PPH}$ and 4,4 - $-\mathrm{BipyH} / \mathrm{H}_{2}$ cations

The electrostatic potential localized on the pyridyl nitrogen atoms of the $4-\mathrm{PPH}$ and 4,4'$\mathrm{BipyH} / \mathrm{H}_{2}$ cations was quantified to assess hydrogen bond donor strength. The 4-PPH cations crystallize in one of two geometries: linear, where both aromatic rings are coplanar and the twisted, where the phenyl ring is contorted out-of-plane relative to the pyridyl ring (Figure S11). The magnitude of the
electrostatic potential of the $\mathrm{N}-\mathrm{H}^{+}$donor is $+581 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in the linear arrangement whereas in the twisted geometry the potential is more positive at $+586 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Table S12).

The $4,4^{\prime}$ ' $\mathrm{BipyH} / \mathrm{H}_{2}$ cations crystallize as a mono or doubly protonated cation. Therefore the $4,4^{\prime}$ 'BipyH can function as either a hydrogen bond donor and acceptor whereas the $4,4^{\prime}-\mathrm{BipyH}_{2}$ can act as a dual donor (Figure S11). The monoprotonated 4,4'-BipyH cation is polar and has a large and positive potential at the $\mathrm{N}-\mathrm{H}^{+}$hydrogen bond donor $\left(+604 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ whereas the non-protonated nitrogen has a smaller potential of $+77 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Table S12). The lone pair located on the non-protonated nitrogen offsets some of the positive potential of the cation, allowing for this region to function as a hydrogen bond acceptor as expected. The doubly protonated cation is not polar as the magnitude of the ESP at both $\mathrm{N}-\mathrm{H}^{+}$donors is $+851 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Based solely upon the magnitudes of the electrostatic potentials we rank the hydrogen bond donor strength of the pyridinium cations as follows: 4- $\mathrm{PP}<4,4^{\prime}$ - $\mathrm{BipyH}<4,4^{\text {' }}$ $\mathrm{BipyH}_{2}$.

Figure S11. Left-to-Right: The electrostatic potential of the $4-\mathrm{PPH}, 4,4$ '- BipyH and $4,4^{\prime}$ - $\mathrm{BipyH}_{2}$ cations.

Table S12. The ESP at the $\mathrm{N}-\mathrm{H}^{+}$hydrogen bond donor sites on the pyridinium cations.

| Region | 4-Phenylpyridine | 4,4-Bipyridinium |
| :---: | :---: | :---: |
|  |  | Monoprotonated |
| $\mathbf{N}-\mathbf{H}^{+}$ | Linear: $+581 \mathrm{~kJ} \mathrm{~mol}^{-1}$ | $\mathrm{~N}:+604 \mathrm{~kJ} \mathrm{~mol}^{-1}$ |
|  | Twisted: $+586 \mathrm{~kJ} \mathrm{~mol}^{-1}$ | N2: $+77 \mathrm{~kJ} \mathrm{~mol}^{-1}$ |
|  |  | Doubly Protonated |
|  |  | $\mathrm{N} 1:+851 \mathrm{~kJ} \mathrm{~mol}^{-1}$ |
|  |  | $\mathrm{~N} 2:+851 \mathrm{~kJ} \mathrm{~mol}^{-1}$ |

## 7. Experimental UV-VIS and Luminescence spectra of 1 - 7

## Sample Preparation for Luminescence and Spectroscopy Analysis:

Co-formation of 1-7 is the norm, yet the crystals are easily differentiated by color. Thus, crystals for spectroscopic analysis were manually separated from the bulk product and (if needed) phase purity was assessed via PXRD.

## Compound 1: $\left(\mathrm{C}_{11} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{5}\right] \cdot \mathbf{3 H}_{\mathbf{2}} \mathrm{O}$

Figure S11. The UV-Vis diffuse reflectance spectrum of $\mathbf{1}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=490 \mathrm{~nm}$ and a maximum at $\lambda=275 \mathrm{~nm}$ that corresponds to the absorbance by the $4-\mathrm{PPH}$ cations.

Figure S12. Luminesence spectra of $\mathbf{1}$ at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (left) and the 4-phenylpyridinium cation $\lambda_{\text {max }}$ of 280 nm (right).

## Compound 2: $\left(\mathrm{C}_{11} \mathrm{H}_{10} \mathrm{~N}\right)_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$

Figure S13. The UV-Vis diffuse reflectance spectrum of $\mathbf{2}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=440 \mathrm{~nm}$ and maxima at $\lambda=277 \mathrm{~nm}$ that correspond to the absorbance by $4-\mathrm{PPH}$.

Figure S14. Luminescence spectra of 2 at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (left) and the 4-phenylpyridinium cation $\lambda_{\text {max }}$ of 286 nm (right).

## Compound 3: $\left[\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{~N}_{2}\right]_{3}\left[\mathrm{UO}_{2}(\mathrm{NCS})_{5}\right]$

Figure S15. The UV-Vis diffuse reflectance spectrum of $\mathbf{3}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=540 \mathrm{~nm}$ and maxima at $\lambda=261 \mathrm{~nm}$ that correspond to the absorbance by $4,4{ }^{\prime}$-BIPYH cations.

Figure S16. Luminescence spectra of $\mathbf{3}$ at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (top left); the spectrum is magnified (right) to highlight the vibronic peaks at $509.5,531.4,557$ and 583.5 nm . Excitation of $\mathbf{3}$ at the $4,4^{\prime}$-Bipy $\lambda_{\text {max }}$ of 250 nm (bottom) results in $4,4^{\prime}$-Bipyridinium fluoresence and phosphoresence.

Diffractogram 1. Crystal of $\mathbf{3}$ were ground in $\mathrm{BaSO}_{4}$ prior to UV-Vis analysis and do not show any signs of a compositional change as a resul of sample preparation. The calculated powder X-ray diffraction pattern based on the single crystal data of $\mathbf{3}$ and $\mathrm{BaSO}_{4}$ are overlain in red and blue, respectively.

## Compound 4: $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathbf{N}_{2}\right)_{1.5}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{5}\right] \cdot \mathbf{2} \mathbf{H}_{\mathbf{2}} \mathrm{O}$

Figure S17. The UV-Vis diffuse reflectance spectrum of $\mathbf{4}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=490 \mathrm{~nm}$ and maxima at $\lambda=251 \mathrm{~nm}$ that correspond to absorption by the $4,4{ }^{\prime}-\mathrm{BipyH}_{2}$ cations.

Figure S18. Luminescence spectra of 4 at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (top left); the spectrum is magnified (right) to highlight the vibronic peaks at 508, 531 and 555 nm . Excitation of 4 at the $4,4^{\prime}$-Bipy $\lambda_{\max }$ of 250 nm (bottom) results in 4, $4^{\prime}$-Bipyridinium phosphoresence.

Compound 5: $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathbf{N}_{2}\right)_{2}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{4}(\mathbf{S C N})_{0.75}(\mathrm{Cl})_{0.25}\right] \cdot(\mathrm{SCN})$

Figure S19. The UV-Vis diffuse reflectance spectrum of $\mathbf{5}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=467 \mathrm{~nm}$ and maxima at $\lambda=264 \mathrm{~nm}$ that correspond to the absorption by $4,4^{\prime}-\mathrm{BipyH}_{2}$ cations.

Figure S20. Luminescence spectra of $\mathbf{5}$ at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (left) and the 4,4'-Dipyridyl $\lambda_{\text {max }}$ of 276 nm (right).

## Compound 6: $\left(\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{~N}_{\mathbf{2}}\right)_{2}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{5}\right] \cdot \mathrm{NO}_{3}$

Figure S21. The UV-Vis diffuse reflectance spectrum of $\mathbf{6}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=448 \mathrm{~nm}$ and $\lambda=254 \mathrm{~nm}$ that correspond to the absorption by the $4,4^{\prime}-\mathrm{BipyH}_{2}$ cations.

Figure S22. The luminescence spectra of 6 at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (top left); the spectrum is magnified (right) to highlight the vibronic peaks at 496, 50, 530.5, 556, 583 and 595.5 nm . Excitation of $\mathbf{6}$ at the $4,4^{\prime}$-Bipy $\lambda_{\text {max }}$ of 250 nm (bottom) results in a $\mathrm{UO}_{2}{ }^{2+}$ and $4,4^{\prime}$-bipyridinium based luminesence.

## Compound 7: $\left(\mathrm{C}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{1 0}} \mathrm{N}_{\mathbf{2}}\right)_{2}\left[\mathrm{UO}_{\mathbf{2}}(\mathrm{NCS})_{4} \mathrm{Cl}\right] \cdot \mathbf{C l} \cdot \mathbf{2} \mathbf{H}_{\mathbf{2}} \mathrm{O}$

Figure S23. The UV-Vis diffuse reflectance spectrum of $\mathbf{7}$ features a $\mathrm{SCN} \rightarrow \mathrm{UO}_{2}{ }^{2+}$ charge transfer band centered at $\lambda=480 \mathrm{~nm}$ and maxima at $\lambda=250 \mathrm{~nm}$ that correspond to the absorption by $4,4{ }^{\prime}-\mathrm{BipyH}_{2}$ cations.

Figure S24. The luminescence spectra of 7 at 77 K upon excitation at the $\mathrm{UO}_{2}{ }^{2+} \lambda_{\text {max }}$ of 420 nm (top left); the spectrum is magnified (right) to highlight the shoulders ( $500,547,573$ and 603 nm ) and the less intense vibronic peaks: 508, 530,556 and 595 nm . Excitation of 7 at the $4,4^{\prime}$-Bipy $\lambda_{\text {max }}$ of 254 nm (bottom) results in 4,4'-bipyridinium luminesence.

## 9. Low Temperature and calculated UV-Vis spectra of 3 and other related information

Photo S3. The crystals of $\mathbf{3}$ are red to 298 K (left) and light orange (right) at 77 K .

Figure S25. The experimental diffuse reflectance spectra of $\mathbf{3}$ at 298 K (red trace) and low-temperature (orange trace).

After the room temperature UV-Vis diffuse reflectance data were collected the specimen (including the sample holder) was immersed in liquid nitrogen for approximately three minutes. The sample holder was quickly removed from the liquid nitrogen and placed into the instrument and data collected. The temperature of the sample holder was recorded at the beginning $\left(-44^{\circ} \mathrm{C}\right)$ and end $\left(-19^{\circ} \mathrm{C}\right)$ of the data collection using a laser infrared thermometer. We note that whereas this experiment is qualitative, the low-temperature spectrum was taken in triplicate, i.e. the sample holder was cooled each time, and the data were nearly identical. Moreover, the experiment was reproducible as the sample was allowed to warm to room temperature between each measurement cycle.

Figure S26. The calculated UV-Vis absorbance spectra of A and B

Figure S27. The calculated UV-Vis absorbance spectra of C and D.
