I. GENERAL SYNTHESIS INFORMATION

All reactions were carried out under ambient atmosphere unless otherwise noted. Room temperature (rt) is defined as 21–23 °C. Tetrahydrofuran (THF), dimethylformamide (DMF), dichloromethane (DCM), and toluene (PhMe) were obtained from Glass Contour Seca Solvent Purification System in which the solvent was dried over alumina and dispensed under an atmosphere of argon. All reagents were obtained from commercial sources and used without further purification.

Infrared spectra were recorded on a Nicolet 6700 ATR/FT-IR spectrometer with ν_{max} partially reported in cm⁻¹. High-resolution liquid chromatography-mass spectrometry (HRMS) was performed by the Mass Spectrometry Laboratory at the University of Illinois at Urbana-Champaign using a Waters Synapt G2-Si instrument equipped with an electrospray ionization (ESI) detector. For crude data analysis, ultra high-performance liquid chromatography-mass spectrometry (UPLC/MS) was performed with a Waters Acquity UPLC/MS instrument equipped with a reversed-phase BEH C18 column (1.7 mm particle size, 2.1 x 50 mm), a dual atmospheric pressure chemical ionization (API)/electrospray ionization (ESI) mass spectrometry detector, and a photodiode array detector. Analytical thin-layer chromatography (TLC) was performed using 60 Å Silica Gel F₂₅₄ pre-coated plates (0.25 mm thickness). TLC plates were visualized by irradiation with a 10, 25, 50, or 100 g SNAP Ultra (HP Sphere, 25 µm silica) cartridge and an appropriate ethyl acetate (EtOAc)/hexanes (Hex), or methanol (MeOH)/dichloromethane (DCM) linear gradient in the mobile phase for normal-phase column chromatography, and 12, 30, 60, or 120 g SNAP-C18 columns with an appropriate methanol (MeOH)/H₂O linear gradient in the mobile phase for reverse-phase column chromatography.

Routine ¹H NMR spectra were recorded on Agilent 500 or 600 MHz spectrometers at ambient temperature. NMR solvents, d-chloroform (CDCl₃), d₄-methanol (CD₃OD), and d_6 -dimethylsulfoxide (DMSO- d_6), were purchased from Cambridge Isotope Laboratories and used without further purification. d-Chloroform was stored at ambient temperature over 4 Å molecular sieves, and fresh DMSO-d₆ and CD₃OD ampules were used immediately after opening. Spectra were processed using MestReNova 10.0.1 using the automatic phasing and polynomial baseline correction capabilities. Splitting was determined using the automatic multiplet analysis function with intervention as necessary. Spectral data are reported as follows: chemical shift (multiplicity [singlet (s), broad singlet (bs), doublet (d), triplet (t), quartet (q), pentet (p), multiplet (m), doublet of doublets (dd), doublet of doublet of doublets (ddd), doublet of triplet of doublets (dtd), doublet of doublet of doublet of doublets (dddd), doublet of triplets (dt), triplet of doublets (td), complex (comp), etc.], coupling constant, integration). Chemical shifts are reported in ppm (δ), and coupling constants are reported in Hz. ¹H Resonances are referenced to solvent residual peaks for CDCl₃ (7.26 ppm), CD₃OD (3.31 ppm), or DMSO-d₆ (2.50 ppm). Routine ¹³C NMR spectra were recorded on Agilent 500 or 600 MHz spectrometers with protons fully decoupled. ¹³C Resonances are reported in ppm relative to solvent residual peaks for CDCl₃ (77.2 ppm), CD₃OD (49.0 ppm), or DMSO-*d*₆ (39.5 ppm). ¹⁹F-NMR spectra were recorded on Agilent 500 MHz spectrometers, and resonances are reported in ppm relative to solvent residual peaks for $CDCl_3$ (77.2 ppm), CD_3OD (49.0 ppm), or DMSO- d_6 (39.5 ppm).

To a solution of benzylamine (4 μ L, 33 μ mol, 2.0 equiv) in toluene/chloroform (4:1 v/v; 100 μ L, 0.16 M), **8b** (7.9 mg, 16 μ mol, 1.0 equiv) was added and stirred at rt for 15 h. Conversion was monitored *via* UPLC/MS. The solution was concentrated in vacuo, then subjected to normal-phase column chromatography (SNAP Ultra-10g column; gradient = 0–10% MeOH/DCM over 10 CV). concentrated *in vacuo*. The solid was resuspended in EtOAc (1 mL), then rinsed with citric acid solution (1 mL, 10% m/v) followed by saturated bicarbonate (1 mL). VI. CRYSTALLOGRAPHY DATA

i. Experimental

Low-temperature diffraction data (ω -scans) were collected on a Rigaku MicroMax-007HF diffractometer coupled to a Dectris Pilatus3R detector with Mo K α (λ = 0.71073 Å) for the structure of amides **7a**, **7b**, **8a**, and **9**. The diffraction images were processed and scaled using Rigaku Oxford Diffraction software.⁴ The structure was solved with SHELXT and was refined against F² on all data by full-matrix least squares with SHELXL.⁵ All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in the model at geometrically calculated positions and refined using a riding model. The isotropic displacement parameters of all hydrogen atoms were fixed to 1.2 times the U value of the atoms to which they are linked (1.5 times for methyl groups).

For **9**, the N-H was semi-freely refined with a distance restraint of 0.88(2) Å. Several reflections were improperly recorded and omitted from the refinement. The program SQUEEZE was used to compensate for the contribution of disordered solvents contained in voids within the crystal lattice from the diffraction intensities. This procedure was applied to the data file and the submitted model is based on the solvent removed data. Based on the total electron density found in the voids (120.5 e/Å³), it is likely that ~2.5 THF molecules, 10 waters, or some combination of these solvents are present in the unit cell. See "_platon_squeeze_details" in this .cif for more information.

Full numbering schemes and additional refinement details for **7a**, **7b**, **8a**, and **9** can be found in the crystallographic information files (.cif), which are provided as supplementary information. The CCDC numbers for **7a** (1897303), **7b** (1895220), **8a** (1895221), and **9** (1895222) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Center *via* www.ccdc.cam.ac.uk/data_request/cif.

V. DFT CALCULATIONS

All DFT calculations were performed using the Gaussian16 program package, with visualization of input and output files accomplished using GausView 6.0.16.⁶ X-ray crystal structures were used as the starting point for ground state geometry optimization. Rotational barriers were derived from a triple- ζ geometry optimization of the stationary points of a relaxed torsional potential energy scan of the N-C(O) axis at the B3LYP/6-311++G(d,p) level, including D3 version of Grimme's dispersion correction.⁷ Gibbs free energies refer to gas phase conditions at standard temperature (298.15 K) and pressure (1 atm). No imaginary frequencies were observed for ground states; transitions states were verified by occurrence of one imaginary frequency (shown below). Their assignment to stationary points was verified by visual inspection and optimization of distorted transition state structures in both directions of the imaginary frequency. In the following sections, the abbreviations GS (ground state) and TS (transition state) are used.
