## General experimental methods.

Solvents were purified and dried by standard procedures. Melting points were recorded in a metal block and are uncorrected. The abbreviation "rt" refers to reactions carried out at a temperature between $21-25^{\circ} \mathrm{C}$. Reaction mixtures were stirred using Teflon-coated magnetic stir bars. High reaction temperatures were maintained using Thermowatch-controlled silicone oil baths. Thin-layer chromatography (TLC) was performed on silica gel plates and components were visualized by observation under UV light, and / or by treating the plates with p-anisaldehyde or cerium nitrate solutions, followed by heating. Flash chromatography was carried out on silica-gel (40-63 $\mu \mathrm{m}$ or 70-200 $\mu \mathrm{m})$. Dryings were performed with anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ or $\mathrm{MgSO}_{4}$. Concentration refers to the removal of volatile solvents via distillation using a Büchi rotary evaporator followed by high vacuum. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at $250,300,400$ and $500 \mathrm{MHz} ;{ }^{13} \mathrm{C}$ NMR spectra were recorded at $62,75,100$ and 125 MHz , with the solvent peak used as the internal reference. DEPT-NMR and two-dimensional experiments (HMQC and HMBC, COSY and NOESY). NMR spectra were analyzed using MestReNova© NMR data processing software (www.mestrelab.com). The following abbreviations are used to indicate signal multiplicity: s, singlet; $d$, doublet; $t$, triplet; $q$, quartet; dd, double doublet; dt, double triplet; m, multiplet; br, broad. $\mathrm{CI}, \mathrm{El}$ and LSIMS mass spectra and high-resolution mass spectra were recorded in an AUTOSPEC-Q mass spectrometer (three sectors high-resolution mass spectrometer with added quadrupole), as well as at the CACTUS facility of the University of Santiago de Compostela.

## Synthesis of gold(I) complexes Au7 and Au8

## 2-CyclohexyInaphthalen-1-ylboronic acid (5b).

Freshly activated Mg turnings ( $340 \mathrm{mg}, 14 \mathrm{mmol}$ ) and a catalytic amount of $\mathrm{I}_{2}$ were placed in a 2necked flask equipped with a condenser under an argon atmosphere. A solution of 1-bromo-2cyclohexylnaphthalene ( $3.40 \mathrm{~g}, 11.7 \mathrm{mmol}$ ) in anhydrous THF ( 14 mL ) was added slowly under a constant reflux. The reaction mixture was stirred for 2 h at rt , then cooled to $-78{ }^{\circ} \mathrm{C}$ and trimethyl borate ( $2.2 \mathrm{ml}, 20 \mathrm{mmol}$ ) was added slowly. The mixture was allowed to warm to rt and stirred overnight. $2 \mathrm{~N} \mathrm{HCl}(5$ ml ) was added and most of the THF was removed under reduced pressure. The mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 3 $\times 10 \mathrm{~mL})$ and the combined organic layer was dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated. Addition of cyclohexane afforded a precipitated that was washed with cold $\mathrm{Et}_{2} \mathrm{O}$, yielding $2.39 \mathrm{~g}(80 \%)$ of $\mathbf{5 b}$ as a white solid. M.p. $156-158{ }^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.83-7.77(\mathrm{~m}, 3 \mathrm{H}), 7.50-7.38(\mathrm{~m}, 3 \mathrm{H}), 4.97(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 2.73(\mathrm{tt}, \mathrm{J}=11.8,3.2 \mathrm{~Hz}, 1 \mathrm{H})$, $1.96-1.74(\mathrm{~m}, 5 \mathrm{H}), 1.73-1.46(\mathrm{~m}, 3 \mathrm{H}), 1.44-1.21(\mathrm{~m}, 2 \mathrm{H}) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(125 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 148.1,134.9,131.6,129.1$, $128.2,127.7,126.2,125.1,124.2,46.3,34.8,26.9,26.1 . \mathrm{m} / \mathrm{z}(E I) 254\left(100, \mathrm{M}^{+}\right), 253\left(25, \mathrm{M}^{+}-1\right), 167(61), 142(28)$. Additional information regarding reaction of (1Z,3E)-2f with 1a (reference 28 main manuscript)

The reaction of $(1 Z, 3 E)$ - 2 f with 1 a under standard conditions at $-50^{\circ} \mathrm{C}$ or even at higher temperatures (allowing the reaction temperature to reach $0^{\circ} \mathrm{C}$ ) did not provide any $(4+2)$ cycloadduct. Only the bis-1a, the allenamide $2+2$ cycloaddition adduct, could be isolated in a modest $24 \%$ yield. This result suggests that a concerted cycloaddition between the diene (in a s-cis conformation) and the gold-allyl cation derived from 1a could be taking place. Both, concerted $(4+2)$ or $(4+3)$ cycloadditions, this later followed by a 1,2-ring contraction, could be equally feasible. references $5 a, b$ and $7 a$ of the main manuscript for related mechanistic information.

## Complementary screening to Table 1, employing other chiral gold complexes.

We also tested phosphoramidite-based chiral gold complexes, previously developed by us in the context of intramolecular allene-diene asymmetric (4+2) and (4+3) cycloadditions. ${ }^{20}$ As shown in Scheme S1, catalyst $(R, R, R)$ $\mathrm{Au} 9 / \mathrm{AgSbF}_{6}(5 \mathrm{~mol} \%)$ promoted the cycloaddition of allenamide 1a with 1-phenyl-1,3-butadiene (2a), affording the desired adduct in $86 \%$ yield and a $60 \%$ ee. However, all attempts to improve this result varying the phosphoramidite and/or the reaction conditions were unsuccessful. Additionally, this catalyst proved to be less effective with dienes incorporating a methyl group at the prochiral center (2d), and completely ineffective with a 1,4-di-substituted diene such as $\mathbf{2 i}$, for which a low yield and poor enantioselectivity were obtained (Scheme S1).

Other frequently used chiral gold complexes such as $\operatorname{DTBM}$-Segphos $(\mathrm{AuCl})_{2} / \mathrm{AgSbF}_{6}$ did also catalyze the cycloaddition of $\mathbf{1 a}$ and $\mathbf{2 a}$ with good yield ( $80 \%$ ) and $77 \%$ ee, but again, its performance with dienes such as $\mathbf{2 b}$ or $\mathbf{2 c}$ was really poor (low yields, low selectivity and ee's).
