## General Experimental Methods

All reactions were performed in oven or flame-dried glassware under a argon atmosphere and stirred magnetically. THF, Et<sub>2</sub>O and toluene were distilled from sodium/benzophenone ketyl prior to use. Triethylamine, diisopropylamine and methylene chloride were distilled from calcium hydride and stored under argon over 4Å molecular sieves. *n*-Butyllithium was titrated against diphenylacetic acid according to the procedure of Kofron and Baclawski.<sup>i</sup> Other reagents and solvents from commercial sources were stored under argon and used directly. Melting points were measured on a capillary melting point apparatus and are uncorrected. Radial preparative layer chromatography (radial PLC) was performed using glass plates coated with 1, 2 or 4 mm layers of Kieselgel 60 PF254 containing gypsum. High-resolution mass spectral analysis (HRMS) was performed at North Carolina State University. Optical rotations were measured on a precision automated polarimeter. NMR spectra were recorded on a 300 or 400 MHz spectrometer. *Chemical shifts* are reported in ppm. Coupling constants (*J* values) are reported in Hertz. IR spectra were recorded on a FT-IR spectrometer. Chemical shifts are in ppm units with TMS (0.0 ppm) used as the internal standard for <sup>1</sup>H NMR spectra and the CDCl<sub>3</sub> absorption of 77.23 ppm for <sup>13</sup>C NMR.
