# Spousal Bargaining Over Care for Elderly Parents in China: Imbalances in Sex Ratios Influence the Allocation of Support 

MARIA PORTER*<br>*Department of Agricultural, Food, and Resource Economics, Michigan State University, East Lansing, MI, USA

## Online Appendix

## 1. Collective Model with Support for Elderly Parents

In the collective model (Chiappori, 1988, 1992), household bargaining takes place between two actors over the allocation of household income $Y$ to individual private consumption $q_{h}$ and $q_{w}$, and a public good $Q$, with a vector of prices $p$. A common form of private consumption is individual leisure, $L_{h}$ and $L_{w}$. An example of a public good is children's wellbeing.

Assuming each spouse has one elderly parent, we include the utility of one's elderly parent as an additional exclusively consumed good. Thus, each spouse cares about his or her own mother but not for the spouse's parent. Indexing husband and wife with $i=h$ or $w$, let us assume the utility of each parent is twice continuously differentiable, strictly increasing, and strictly concave in $q_{m}^{i}$, her private consumption; $q_{i}$, her child's individual consumption; $L_{i}$, her child's amount of leisure time; and $c_{i}$, the amount of time her child spends supporting her net of any support she provides to her child, such as grandchild care, which can be positive or negative. For example, parents often take care of grandchildren. Spouse utility is then $U_{i}\left(q_{i}, L_{i}, U_{m}^{i}\left(q_{m}^{i}, c_{i}, q_{i}, L_{i}\right), Q\right)$.

Husband and wife allocate household income to the consumption bundle $\left\{q_{h}, q_{w}, L_{h}, L_{w}, c_{h}, c_{w}, q_{m}^{h}, q_{m}^{w}, Q\right\}$. Let total household income $(Y)$ equal the sum of spouse income $y_{h}$ and $y_{w}$, and when the couple lives with the husband's mother $(j=t)$, her income $y_{m}^{h}$. Otherwise, when the couple lives on their own $(j=a)$, the husband's mother does not pool her income with theirs. In China, because it is rare for the wife's parents to live with the couple, this possibility is not modelled.

Since the husband's mother only pools her income with the couple's when she lives with them, her participation constraint is only relevant in this circumstance $(j=t)$. Her utility from living with her son and daughter-in-law, and accepting the consumption bundle they choose must be at least as great as her reservation utility $\bar{U}_{m}^{h}$, which is a function of her own income $\left(y_{m}^{h}\right)$. Implications derived from this model are the same irrespective of whether this constraint binds.

With this participation constraint, the parent is an active decision-maker. The Lagrange multiplier on this participation constraint is equivalent to the Pareto weight in a collective model where parents also bargain with children (Ham and Song, 2014).

Predictions are derived from first order conditions on the amount of support provided to each parent ( $c_{h}$ and $c_{w}$ ). For husbands and wives, how much time to spend supporting their parents involves a
trade-off between the indirect utility from providing such support and the utility from leisure or wage income, $w_{h} l_{h}$ and $w_{w} l_{w}$. Time constraints reflect this trade-off.

The central assumption of the collective model is that allocation decisions are Pareto efficient:

$$
\begin{align*}
& \left\{q_{h}^{j} q_{w}^{j}, c_{h}^{j}, c_{w}^{j}, q_{m}^{\left.h_{j}^{j}, q_{m}^{w j}, Q^{j}\right\}}\right.  \tag{A1}\\
& +\mu^{j}(R) U_{w}\left(q_{w}^{j}, L_{w}^{j}, U_{m}^{w}\left(q_{h}^{w j}, L_{h}^{j}, U_{m}^{j}, q_{w}^{j}, q_{m}^{h j}, c_{h}^{j}, q_{h}^{j}, L_{h}^{j}\right), Q^{j}\right) \\
& \left.Q^{j}\right)
\end{align*}
$$

subject to:

$$
\begin{gather*}
p\left(q_{h}^{j}+q_{w}^{j}+q_{m}^{h j}+q_{m}^{w j}+Q^{j}\right) \leq Y^{j} \\
=y_{h}^{j}+y_{w}^{j}+(D=0, j=a ; D=1, j=t) \cdot y_{m}^{h}  \tag{A2}\\
=w_{h} l_{h}^{j}+w_{w} v_{w}^{j}+(D=0, j=a ; D=1, j=t) \cdot y_{m}^{h} \\
l_{h}^{j}+L_{h}^{j}+c_{h}^{j} \leq T  \tag{A3}\\
p_{w}^{j}+L_{w}^{j}+c_{w}^{j} \leq T \\
U_{m}^{h}\left(q_{m}^{h t}, c_{h}^{t}, q_{h}^{t}, L_{h}^{t}\right) \geq \bar{U}_{m}^{h}\left(y_{m}^{h}\right) \tag{A4}
\end{gather*}
$$

The Pareto weight $\mu$ is a continuously differentiable function of spouses' non-labour incomes and distribution factors (Blundell et al., 2005). The latter influence outcomes only through the decision process and do not affect individual preferences over consumption. In this case, the distribution factor is the sex ratio at marriage $(R)$.

For $j=a, t$, let $V^{j}=U_{h}\left(q_{h}^{j *}, L_{h}^{j *}, U_{m}^{h}\left(q_{m}^{h j *}, c_{h}^{j *}, q_{h}^{i *}, L_{h}^{j *}\right), Q^{i *}\right)+\mu^{j}\left(R^{j}\right) U_{w}\left(q_{w}^{j *}, L_{w}^{i *}, U_{m}^{w j *}\left(q_{m}^{w j *}\right.\right.$, $\left.c_{w}^{j *}, q_{w}^{j *}, L_{w}^{j *}, Q^{i *}\right)$,
where $\left\{q_{h}^{j *}, q_{w}^{j *}, L_{h}^{j *}, L_{w}^{j *} q_{m}^{h j *}, q_{m}^{w j *}, c_{h}^{j *}, c_{w}^{j^{*}}, Q^{i *}\right\}$ is the optimum consumption bundle determined by the household maximisation problem for $j=a$ or $t$. The household then determines whether to live with the husband's mother:

$$
\begin{equation*}
V^{*}=\max \left\{V^{a}, V^{t}\right\} \tag{A5}
\end{equation*}
$$

Budget and time constraints yield the full income budget constraint:

$$
\begin{align*}
& p\left(q_{h}^{j}+q_{w}^{j}+q_{m}^{h j}+q_{m}^{w j}+Q^{j}\right) \leq  \tag{A6}\\
& w_{h}\left(T-c_{h}^{j}-L_{h}^{j}\right)+w_{w}\left(T-c_{w}^{j}-L_{w}^{j}\right)+(D=0, j=a ; D=1, j=t) \cdot y_{m}^{h}
\end{align*}
$$

This is similar to a standard set-up of the collective model. In addition to the standard results from a collective model with two exclusive goods and one public good (Blundell et al., 2005), first order conditions imply:

Proposition 1: As a woman's bargaining power ( $\mu^{j}$ ) increases:
(i) Time spent supporting her husband's mother $\left(c_{h}^{j}\right)$ declines
and/or
(ii) Time spent supporting her own mother $\left(c_{w}^{j}\right)$ rises.

Proof. With $\lambda^{j}$ being the Lagrange multiplier on Equation (A6) and $\rho$ being the Lagrange multiplier on Equation (A4), first order conditions on $c_{h}^{j}$ and $c_{w}^{j}$ imply:

$$
\begin{gather*}
\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial{c_{h}^{j}}_{j}^{j}}=\lambda^{j} w_{h}+\rho \frac{\partial U_{m}^{h}}{\partial c_{h}^{j}}  \tag{A7}\\
\mu^{j} \frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{j}}=\lambda^{j} w_{w} \tag{A8}
\end{gather*}
$$

When $\rho=0$, that is, the participation constraint of the husband's mother is not binding, combining these two conditions yields:

$$
\begin{equation*}
\frac{\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{\prime}}}{\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{m}}}=\mu^{j} \frac{w_{h}}{w_{w}} \tag{A9}
\end{equation*}
$$

Equation (A9) indicates that the marginal rate of substitution (MRS) between support provided to each parent equals the ratio between the spouses' wages, weighted by $\mu^{j}$.

Let us assume this MRS is functionally independent from quantities of other goods, namely, adult children's consumption, leisure, and parents' consumption. For $i=h, w$, let $U_{m}^{i}\left(q_{m}^{i j}, c_{i}^{j}, q_{i}^{j}, L_{i}^{j}\right)=$ $U_{m}^{i}\left(c_{i}^{j}, v\left(q_{m}^{i j}, q_{i}^{j}, L_{i}^{j}\right)\right)$. By definition, $c_{h}^{j}$ and $c_{w}^{j}$ are weakly separable from $Q$, and $\left\{q_{m}^{h j}, c_{h}^{j}, q_{h}^{j}, L_{j}^{j}\right\}$ are strongly separable from $\left\{q_{m}^{w j}, c_{w}^{j}, q_{w}^{j}, L_{w}^{j}\right\}$. This additional assumption of weak separability of $c_{i}^{j}$ from $q_{m}^{i j}, q_{i}^{j}$, and $L_{i}^{j}$ allows us to restrict the analysis to focus on $c_{h}^{j}$ and $c_{w}^{j}$ without examining other goods (Deaton and Muellbauer, 1980; Browning and Meghir, 1991).

Equation (A9) implies that holding wages constant, increasing $\mu^{j}$ would raise the numerator and/or decrease the denominator. Then, $c_{h}^{j}$ decreases and/or $c_{w}^{j}$ increases.

Now we show this holds when $\rho>0$, where Equation (A7) and Equation (A8) imply:

$$
\left(\frac{\frac{\partial U_{m}^{h}}{\partial c_{h}^{h}}}{\frac{\partial U_{m}^{w}}{\partial c_{w}^{w}}}\right)\left(\frac{\frac{\partial U_{h}}{\partial U_{m}^{h}}-\rho}{\frac{\partial U_{w}}{\partial U_{m}^{w}}}\right)=\mu^{j} \frac{w_{h}}{w_{w}}
$$

The utility of each child is increasing in the utility of the child's parent, $\frac{\partial U_{h}}{\partial U_{m}^{h}}>0$ and $\frac{\partial U_{w}}{\partial U_{m}^{w}}>0$. Since the terms on the right-hand side (RHS) are non-negative, the RHS is non-negative, and the left-hand side (LHS) is also non-negative. As the adult child's utility is increasing in the support provided to the child's parent, $\frac{\partial U_{m}^{h}}{\partial c_{h}^{\prime}}>0$ and $\frac{\partial U_{m}^{w}}{\partial c_{w}^{\prime}}>0$, the first term on the LHS is positive. Since the denominator of the second term on the LHS is also positive, the numerator must be non-negative, and $\frac{\partial U_{h}}{\partial U_{m}^{h}}-\rho \geq 0$. Thus, $\rho \leq \frac{\partial U_{h}}{\partial U_{m}^{h}}$, and $q_{m}^{i j}$ and $q_{i}^{j}$ by separability. Thus, if $\mu^{j}$ increases, $\frac{\partial U_{m}^{h}}{\partial c_{h}^{l}}$ rises and/or $\frac{\partial U_{m}^{w}}{\partial c_{w}^{c}}$ declines. By diminishing marginal utility, this implies that $c_{h}^{j}$ declines and/or $c_{w}^{j}$ rises when $\mu^{j}$ increases. Q.E.D.

From Proposition 1, since $\mu$ is an increasing function of the sex ratio $R$, we test whether the likelihood of supporting the husband's (wife's) parents is negative (positive) with respect to $R$.

We also test whether $R$ is positively related to the likelihood of couples living on their own rather than living with the husband's mother, namely:

Proposition 2: Since the wife cares more about her mother than her husband's mother, in equilibrium, the decision to co-reside with the husband's mother is a result of the wife's lower bargaining power:

$$
\mu^{a}>\mu^{t}
$$

Proof. Let us assume that time supporting the husband's mother is greater when the couple lives with her than when they live alone, and time spent supporting the wife's mother is lower when the couple lives with the husband's mother than it would be when they live on their own:

$$
c_{h}^{t}>c_{h}^{a} \text { and } c_{w}^{t}<c_{w}^{a}
$$

By diminishing marginal utility,

$$
\frac{\partial U_{m}^{h}}{\partial c_{h}^{a}}>\frac{\partial U_{m}^{h}}{\partial c_{h}^{t}} \text { and } \frac{\partial U_{m}^{w}}{\partial c_{w}^{a}}<\frac{\partial U_{m}^{w}}{\partial c_{w}^{t}}
$$

Multiplying both sides by $\frac{\partial U_{h}}{\partial U_{m}^{h}}$ and $\frac{\partial U_{w}}{\partial U_{m}^{w}}$ yields:

$$
\begin{aligned}
\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{a}} & >\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{t}} \\
\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{a}} & <\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{t}}
\end{aligned}
$$

Combining these inequalities:

$$
\frac{\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{a}}}{\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{w}^{w}}{\partial c_{w}^{a}}}>\frac{\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{l}}}{\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{t}}}
$$

This inequality and Equation (A9) imply:

$$
\mu^{a}>\mu^{t}
$$

Since this inequality holds under Equation (A9), and since Equation (A9) holds when $\rho=0$, we have shown this inequality to hold when the participation constraint of the husband's mother is not binding.

Now we show it also holds when $\rho>0$. With separability, Equation (A7) and Equation (A8) imply:

$$
\begin{align*}
& \frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{j}}>\lambda^{j} w_{h} \\
& \frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{j}}  \tag{A10}\\
& \frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{j}}>\mu^{j} \frac{w_{h}}{w_{w}}
\end{align*}
$$

Rearranging terms yields:

$$
\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{j}}>\mu^{j} \frac{w_{h}}{w_{w}} \frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{j}}
$$

Under the assumption $c_{h}^{t}>c_{h}^{a}$ and $c_{w}^{t}<c_{w}^{a}$, by diminishing marginal utility:

$$
\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{t}}<\frac{\partial U_{h}}{\partial U_{m}^{h}} \frac{\partial U_{m}^{h}}{\partial c_{h}^{a}} \text { and } \frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{t}}>\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{a}}
$$

Combining inequalities:

$$
\begin{equation*}
\frac{\frac{\partial U_{h}}{\partial U_{m}^{n}} \frac{\partial U_{m}^{h}}{\partial c_{n}^{m}}}{\frac{\partial U_{w}}{\partial U_{w}^{w}} \frac{\partial U_{m}^{w}}{\partial c_{w}^{w}}}>\frac{\frac{\partial U_{h}^{h}}{\partial U_{m}^{n}} \frac{\partial U_{m}^{n}}{\partial c_{n}^{n}}}{\frac{\partial U_{w}}{\partial U_{m}^{w}} \frac{\partial U_{w}^{w}}{\partial c_{w}^{m}}} \tag{A11}
\end{equation*}
$$

$$
\mu^{a}>\mu^{t}
$$

Since $\mu^{a}>\mu^{t}$ would hold if and only if $R^{a}>R^{t}$, we test this proposition by examining whether the partial derivative of the likelihood of the couple living with the husband's parents with respect to $R$ is negative.

## 2. Tables

Table A1. Summary statistics of regressors

| Variable | Obs | Mean | SD | Min | Max |
| :--- | :--- | ---: | ---: | ---: | ---: |
| Variables from Population Census |  |  |  |  |  |
| Male sex ratio | 1682 | 104.8 | 12.3 | 76 | 159 |

Notes: ${ }^{* * *} \mathrm{p}<0.01,{ }^{* *} \mathrm{p}<0.05, * \mathrm{p}<0.1^{\text {a }}$ Logit regressions could not be estimated for this smaller sample due to lack of convergence; instead, reported estimates are based on probits. Note that for the main regressions reported earlier, estimates are similar when a probit is used instead. Robust standard errors in parentheses, clustered by urban/rural and province of birth. Same samples and regressors as in main regressions (Model 4 in the article) unless otherwise noted.
